

# Organic Chemistry: Hyperconjugation, Hydrogen Bonding, and Tautomerism

## Practice Problems on Hyperconjugation, Hydrogen Bonding, and Tautomerism

### 1. Hyperconjugation

Hyperconjugation is an electronic effect that involves the interaction between the sigma bond (usually C-H or C-C) and an adjacent p-orbital or  $\pi$ -bond. This interaction stabilizes the molecule by delocalizing electron density.

#### Influence of Hyperconjugation on the Strength of Acids

Hyperconjugation can significantly affect acidity by stabilizing the conjugate base. When hyperconjugation stabilizes the conjugate base more than the parent acid, the acid becomes stronger.

For example, the acidity order of alkanes follows: tertiary C-H > secondary C-H > primary C-H. This is because the conjugate bases (carbanions) are stabilized by hyperconjugation from adjacent C-H bonds.

**Mechanism:** When a proton is removed from a carbon atom, the resulting carbanion has a negative charge. Adjacent C-H bonds can donate electron density to this negative charge through hyperconjugation, distributing the charge and stabilizing the anion.

**Practice Problem 1:** Arrange the following compounds in order of increasing acidity and explain using hyperconjugation:

- $\text{CH}_3\text{CH}_2\text{CH}_3$  (propane)
- $\text{CH}_3\text{CH}(\text{CH}_3)_2$  (isobutane)

- $(\text{CH}_3)_3\text{CH}$  (2,2-dimethylpropane)

**Practice Problem 2:** Explain why 2-butyne ( $\text{CH}_3\text{C}\equiv\text{CCH}_3$ ) is more acidic than propyne ( $\text{CH}_3\text{C}\equiv\text{CH}$ ) using hyperconjugation concepts.

**Practice Problem 3:** Compare the acidity of cyclopentadiene and cyclopentane using hyperconjugation to explain the difference.

## 2. Hydrogen Bonding

Hydrogen bonding is a type of dipole-dipole interaction that occurs between a hydrogen atom bonded to a highly electronegative atom (like O, N, or F) and another electronegative atom with a lone pair of electrons.

### Influence of Hydrogen Bonding on the Strength of Acids

Hydrogen bonding can affect acid strength by:

- Stabilizing the conjugate base through intermolecular hydrogen bonding
- Enhancing the polarity of the acidic bond
- Facilitating proton transfer in solution

Acids that can form strong hydrogen bonds in their conjugate base forms tend to be stronger acids, as the energy released from hydrogen bond formation helps offset the energy required for deprotonation.

**Example:** Carboxylic acids ( $\text{RCOOH}$ ) are stronger acids than alcohols ( $\text{ROH}$ ) partly because the carboxylate anion ( $\text{RCOO}^-$ ) can form stronger hydrogen bonds with water than alkoxide ions ( $\text{RO}^-$ ).

**Practice Problem 4:** Explain why acetic acid ( $\text{CH}_3\text{COOH}$ ) is more acidic than ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) using hydrogen bonding concepts.

**Practice Problem 5:** Arrange the following compounds in order of increasing acidity and explain using hydrogen bonding:

- $\text{H}_2\text{O}$  (water)
- $\text{H}_2\text{S}$  (hydrogen sulfide)

- $\text{H}_2\text{Se}$  (hydrogen selenide)

**Practice Problem 6:** Compare the acidity of phenol and cyclohexanol in water. How does hydrogen bonding contribute to their difference in acidity?

## Influence of Hydrogen Bonding on the Strength of Bases

Hydrogen bonding also affects base strength by:

- Determining the stability of the protonated base
- Affecting the availability of the lone pair for protonation
- Influencing solvation effects

Bases that can form multiple hydrogen bonds with solvent molecules may have their basic sites "shielded," reducing their basicity. Conversely, bases that form strong hydrogen bonds with the protonated form can enhance stability and increase basicity.

**Practice Problem 7:** Explain why pyridine ( $\text{C}_5\text{H}_5\text{N}$ ) is a weaker base than piperidine ( $\text{C}_5\text{H}_{11}\text{N}$ ) in water, considering hydrogen bonding effects.

**Practice Problem 8:** Compare the basicity of trimethylamine and ammonia in aqueous solution, explaining the role of hydrogen bonding.

## 3. Tautomerism

Tautomerism is a form of isomerism where isomers (called tautomers) readily interconvert by the migration of a hydrogen atom accompanied by a switch of a single bond and adjacent double bond.

### Influence of Tautomerism on the Strength of Acids

Tautomerism can dramatically affect acid strength because different tautomeric forms may have very different acidities. The overall acidity of a compound that exists as a mixture of tautomers will be an average weighted by the relative abundance of each tautomer.

**Key Concept:** In many cases, a compound may exist predominantly in a less acidic form but show enhanced acidity because a small amount exists in a more acidic tautomeric form.

The classic example is acetone, which exists primarily in the keto form but shows enhanced acidity because a small amount exists in the enol tautomer, which is more acidic:

**Practice Problem 9:** Phenol ( $\text{C}_6\text{H}_5\text{OH}$ ) is much more acidic than cyclohexanol. Explain this difference considering the potential for tautomerism in phenol.

**Practice Problem 10:** Compare the acidity of acetylacetone (pentane-2,4-dione) and acetone. Explain why acetylacetone is much more acidic using tautomerism concepts.

**Practice Problem 11:** Nitromethane ( $\text{CH}_3\text{NO}_2$ ) is surprisingly acidic for a compound without an OH group. Explain this acidity in terms of tautomerism and resonance.

### Influence of Tautomerism on the Strength of Bases

Tautomerism also affects base strength as different tautomeric forms may have different basic sites with varying electron densities.

For example, imidazole can exist in two tautomeric forms, each with a different nitrogen atom serving as the basic site. The overall basicity is determined by the contribution of both forms.

**Practice Problem 12:** Explain why 2-pyridone is less basic than 2-hydroxypyridine using tautomerism concepts.

**Practice Problem 13:** Compare the basicity of cytosine and its tautomers in DNA. Which tautomer is more basic and why?

### Detailed Explanations

#### ▼ Explanation for Problem 1:

The order of acidity is:  $(\text{CH}_3)_3\text{CH} > \text{CH}_3\text{CH}(\text{CH}_3)_2 > \text{CH}_3\text{CH}_2\text{CH}_3$

This is because when a proton is removed, the resulting carbanion is better stabilized by hyperconjugation when there are more alkyl groups attached to the carbanionic center.

Tertiary carbanions have more adjacent C-H bonds that can participate in hyperconjugation compared to secondary and primary carbanions.

#### ▼ Explanation for Problem 4:

Acetic acid ( $\text{CH}_3\text{COOH}$ ) is more acidic than ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) because:

- The carboxylate anion ( $\text{CH}_3\text{COO}^-$ ) can delocalize the negative charge through resonance between the two oxygen atoms
- The carboxylate anion forms stronger hydrogen bonds with water molecules than the alkoxide ion ( $\text{CH}_3\text{CH}_2\text{O}^-$ )
- The carbonyl oxygen in carboxylate is more electronegative than the alkyl-substituted oxygen in alkoxide, making hydrogen bonds stronger

These factors stabilize the conjugate base of acetic acid more effectively, making it a stronger acid.

#### ▼ Explanation for Problem 10:

Acetylacetone (pentane-2,4-dione) is much more acidic than acetone because:

- Acetylacetone exists in a significant amount as its enol tautomer due to the stability gained from intramolecular hydrogen bonding
- When deprotonated, the resulting enolate anion is stabilized by delocalization of the negative charge across both carbonyl groups
- This extensive delocalization through resonance is not possible in acetone, which has only one carbonyl group

The  $\text{pK}_a$  of acetylacetone is around 9, while acetone's  $\text{pK}_a$  is about 20, demonstrating the dramatic effect of tautomerism on acidity.

## Advanced Concepts: Combined Effects

In real-world examples, the effects of hyperconjugation, hydrogen bonding, and tautomerism often work together to determine the overall acid or base strength.

### Practice Problem 14:

Explain how hyperconjugation, hydrogen bonding, and potential tautomerism all contribute to the acidity difference between ethanol and 2,2,2-trifluoroethanol.

### Practice Problem 15:

Phenylacetylene ( $\text{C}_6\text{H}_5\text{C}\equiv\text{CH}$ ) is more acidic than acetylene ( $\text{HC}\equiv\text{CH}$ ). Explain this observation using concepts of hyperconjugation, resonance, and inductive effects.

## Practice Problem 16:

Compare the base strength of pyrrole and pyridine, explaining how tautomerism, aromaticity, and hydrogen bonding all play roles in their different basicities.

## Summary of Key Points

| Effect           | Influence on Acids                                                    | Influence on Bases                                           |
|------------------|-----------------------------------------------------------------------|--------------------------------------------------------------|
| Hyperconjugation | Stabilizes conjugate bases, especially carbanions, increasing acidity | Can stabilize protonated forms of bases, increasing basicity |
| Hydrogen Bonding | Stabilizes conjugate bases through solvation, increasing acidity      | Can shield basic sites or stabilize protonated forms         |
| Tautomerism      | Allows access to more acidic tautomeric forms                         | Enables different basic sites with varying strengths         |

**Important Note:** When solving problems involving acid-base properties, always consider:

- The structure of both the acid/base and its conjugate
- Possible resonance and tautomeric forms
- Solvent effects and hydrogen bonding interactions
- Inductive and hyperconjugative effects
